Harbor Pulse

From messy terminal events to defensible decisions

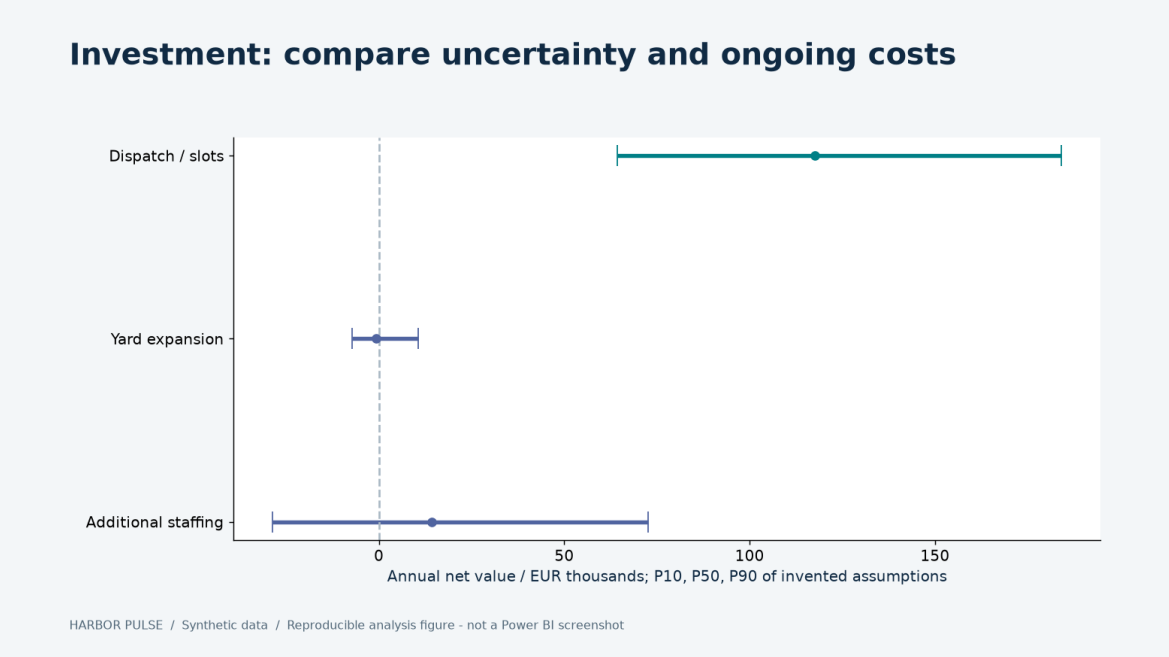

Philippe Godfroy | AI-assisted synthetic portfolio case

THE BUSINESS QUESTION

How can terminals reduce delay without overstating savings or losing trust in data?

WHAT THE CASE BUILDS

Python + SQLite: versioned ingestion, quarantine, reconciliation and replay.
Power BI + weighted DAX: daily operations, quality, scenarios and decision support.
Investment comparison and pilot design: explicit costs, uncertainty and guardrails.

RECOMMENDATION: PILOT DISPATCH FIRST

Under invented assumptions. No realized savings or real intervention effect is claimed.

EVIDENCE THAT CAN BE REVIEWED

366,910 vehicle units | 36 late revisions | 216 duplicates skipped | 0 reconciliation gap
Executable tests, CI, SQL/DAX examples, sensitivity, diagnostics and recovery evidence.

SCOPE AND LIMITS

All source records and outcomes are fictitious. Native terminal roles are deployed.
Power BI screenshots/pixel review are online. RLS viewer tests remain license-blocked.
